CSIE4105 Database Systems

Homework #4

Due on 01/03/2023

- 1. (20%) Consider the universal relation $R = \{A, B, C, D, E, F, G, H, I, J\}$ and the set of functional dependencies $F = \{\{A, B\} \rightarrow \{C\}, \{B, D\} \rightarrow \{E, F\}, \{A, D\} \rightarrow \{G, H\}, \{A\} \rightarrow \{I\}, \{H\} \rightarrow \{J\}\}\}$.
 - (a) (4%) What is the key for R? Explain your answer.
 - (b) (8%) Decompose R into 2NF.
 - (c) (8%) Based on your result in (b), decompose R into 3NF.
- 2. (20%) Consider the relation R, which has attributes that hold schedules of courses and sections at a university; R = {Course_no, Sec_no, Offering_dept, Credit_hours, Course_level, Instructor_ssn, Semester, Year, Days_hours, Room_no, No_of_students}. Suppose that the following functional dependencies hold on R:

- (a) (5%) What normal form is the relation in? Explain your answer.
- (b) (3%) Try to determine which sets of attributes form **keys** of R.
- (c) (12%) Apply normalization until you cannot decompose the relations further. **State the reasons behind each decomposition.**
- 3. (40%) Consider a disk with block size B = 512 bytes. A block pointer is P = 6 bytes long, and a record pointer is $P_R = 7$ bytes long. A file has r = 30,000 EMPLOYEE records of *fixed length*. Each record has the following fields: **Name** (30 bytes), **Ssn** (9 bytes), **Department_code** (9 bytes), **Address** (40 bytes), **Phone** (10 bytes), **Birth_date** (8 bytes), **Sex** (1 byte), **Job_code** (4 bytes), and **Salary** (4 bytes, real number). An additional byte is used as a *deletion marker*.
 - (a) (4%) Calculate the record size R in bytes (including the *deletion marker*).
 - (b) (6%) Calculate the blocking factor bfr and the number of disk blocks b, assuming an **unspanned** organization.
 - (c) (15%, each 5%) Suppose that the file is *ordered* by the key field Ssn and we want to construct a *primary index* on Ssn. Calculate (i) the index blocking factor *bfri* (which is also the index fan-out *fo*); (ii) the number of first-level index entries and the number of first-level index blocks; (iii) the number of levels needed if we make it into a multilevel index; (iv) the total number of blocks required by the multilevel index; and (v) the number of block accesses needed to search for and retrieve a record from the file—given its Ssn value—using **the primary index**.
 - (d) (15%, each 5%) Suppose that the file is *not ordered* by the key field Ssn and we want to construct a *secondary index* on Ssn. Repeat the previous exercise (part c) for the secondary index.

4.	(20%) What are the differences among the primary , secondary , and clustering indexes?
